Abstract: We report photonic RF fractional Hilbert transformers and filters based on a 49GHz soliton crystal micro-comb source. By employing up to 80 wavelengths and controlling the channel weights, diverse transfer functions are achieved.

1. Introduction

Photonic RF filters have attracted great interest during the past two decades, due to advantages including large operation bandwidths, highly reconfigurable filter shapes, as well as rapid tunability and strong immunity to electromagnetic interference [1-2]. A wide range of photonic RF filters have been proposed using either coherent or incoherent structures, [2] and made decent advances such as achieving narrow bandwidths down to the MHz level. The micro-comb sources [3], particularly those based on CMOS-compatible platforms [3], offer distinct advantages over traditional multi-wavelength sources, such as the potential to provide a much higher number of wavelengths as well as greatly reduced footprint and complexity [4-8]. To miniaturize photonic RF filters and enhance the performance, we employ an integrated microcomb source to establish parallel wavelength channels for the transversal and channelized filters. A coherent soliton crystal microcomb was employed, which offers a low free spectral range of 49 GHz that supports up to 80 channels in the optical C band.

Here, we demonstrate photonic RF fractional signal processors including Hilbert transformers (HT) [8], and RF filters using 80-tap transversal structures [9] and channelized structures that have 117 MHz resolution [10]. By arbitrarily controlling the weights of the wavelength channels, diverse transfer functions were achieved, including fractional HTs with tunable fractional orders, lowpass, Gaussian-apodized filters, and bandpass filters with tunable centre frequencies and bandwidths. For the fractional signal processor, orders ranging from 0.166 to 1 are achieved with an operation bandwidth of 16.45GHz. For the transversal filter, a 4-time Q factor enhancement was achieved (in contrast to previously demonstrated 20-tap microcomb based filter [5]), together with tunable centre frequencies and an out-of-band rejection ratio up to over 48 dB. The channelized filter shows a resolution of 117 MHz, together with reconfigurable filtering shapes. The experimental results match well with theoretical calculations, verifying the feasibility of our approach.

2. Theory and experimental results

To generate Kerr micro-combs, the pump power was amplified to ~30.5 dBm and the wavelength was swept across a resonance of the active MRR. As the detuning was changed, distinctive ‘fingerprint’ optical spectra of soliton crystals were observed. The generated comb was spectrally shaped by two stages of Waveshapers (Finisar, 4000S) to precisely achieve desired channel weights. Then the input RF signal was multi-cast onto each comb line via an electro-optical modulator. To achieve transversal structures (Fig. 1), the RF input was broadcast via an intensity modulator and progressively delayed by a spool of single-mode fibre to achieve the required taps. As a result, a high spectral resolution was achieved for both the filter and the HT, together with a significantly improved tunable centre frequency covering the RF spectra range and a high out-of-band rejection of 48.9 dB (Fig. 2(g, h)) for the former, and a reconfigurable fractional order from 0.166 to 1 for the latter (Fig. 2(a-f)). To achieve channelized filters, the RF input was broadcast via a phase modulator and fed to the passive MRR for spectral slicing. The through-port transmission of the passive MRR was employed to perform phase-to-intensity modulation conversion by filtering out the lower sideband and, at the same time, serves as a high-Q Vernier comb filter for high-resolution RF bandwidth scaling. As shown in Fig. 2(i, j), programmable arbitrary transfer functions for RF spectral shaping with an operation bandwidth of 4.64 GHz, together with a high resolution of 117 MHz were achieved. Finally, we note that more compact dispersive devices can be achieved, even offering tunability, with many approaches including etalon tunable dispersion compensators [11-15].

Fig. 1. (a) Schematic diagram of the photonic RF transversal filter based on an integrated 49GHz-spacing micro-comb source. EDFA: erbium-doped fiber amplifier. PC: polarization controller. MRR: micro-ring resonator. ZMZ: Mach-Zehnder modulator. SMF: single mode fiber. PD: photodetector. PM: phase modulator. Demonstrated performance enhancement of (b) the transversal filter's Q factor, (c) the discrepancies in the HT's amplitude responses, (d, e) operation bandwidth of the channelized filters.

3. Conclusions

We have demonstrated photonic RF signal processors based on soliton crystal microcombs. This approach offers a greatly reduced footprint, lower complexity, and potentially lower cost, representing a solid step towards the miniaturization of high performance photonic RF systems [16-25].
